According to the World Health Organisation (WHO) in 2017:

- **1.6 MILLION** people died from TB
- **10.0 MILLION** people estimated to have fallen ill with TB
- **25%** of the world’s TB cases were in the African region

**Tuberculosis (TB)** is a disease caused by germs called bacteria. TB usually affects the lungs, but it can also affect other parts of the body, such as the brain, kidneys or spine. TB kills more people than any other single infectious disease agent in the world.

TB bacteria are spread through the air when a person with TB disease of the lungs or throat coughs, sneezes, laughs, or sings. People nearby may breathe in the TB bacteria and become infected.

**How is TB spread?**

People can be infected with the germ that causes TB, but not feel sick. This is called **latent TB infection**. People with latent TB don’t spread TB germs. About 1 in 3 people in the world (2 billion people) have latent TB.

A person with latent TB may develop active TB disease. This happens to about 1 in 10 people with latent TB, but more often for people who have other health risks, such as HIV or diabetes. Latent TB can become active TB disease right away or years later. Once people have active TB disease, they start to feel sick and can spread TB germs to others.

For more information about TB vaccines visit our website [www.iavi.org](http://www.iavi.org)
It is effective in preventing severe TB in infants and young children, and is not usually effective in protecting high-risk adults and teenagers from getting and spreading TB of the lungs. To protect our communities, we need a better TB vaccine.

**What is a vaccine?**
A vaccine is usually given as an injection to help prevent or fight a disease. Vaccines work by teaching the body how to stop germs, like the TB bacteria, from making people sick. Vaccines are usually given to healthy people who might be exposed to the germ in the future.

**Bacille Calmette-Guerin (BCG)** has been used since 1921 but has not stopped TB.

**Is a TB vaccine available yet?**

1921

It is effective in preventing severe TB in infants and young children, and is not usually effective in protecting high-risk adults and teenagers from getting and spreading TB of the lungs. To protect our communities, we need a better TB vaccine.

**When will a new vaccine be available?**

A new vaccine will be available as soon as we find one that is EFFECTIVE and SAFE.

We cannot tell exactly when a new TB vaccine will be available. Right now, we are running many clinical trials and our goal is to have a new vaccine ready in the next 10 years.

**How are places for conducting clinical trials chosen?**

The very first clinical trials are usually held in the country where the vaccine was first discovered. After a vaccine is first tested for safety, it needs to be tested in countries where the disease is common to see if it prevents disease in the people who need it most. For TB vaccine trials, this needs to be a community with high rates of TB.

**Why is it important for communities to support TB Vaccine development?**

TB causes a great deal of suffering and some forms of TB (drug resistant TB) are hard to cure with current medicine.

A new vaccine is expected to protect against all types of TB.

Clinical trials are helping to create a new TB vaccine that will be used to keep everyone safe and healthy.

TB clinical trials are only possible with cooperation, participation and support from the community.
